

BrightMEM Preloaded™ Corneal Allograft

Ocular surface reconstruction with BrightMEM Preloaded™ corneal allografts, a foundation for durable epithelial regeneration

BrightMEM anterior keratoplasty (DMAK) is a surgical procedure in which a BrightMEM Preloaded™ corneal allograft is transplanted onto the ocular surface to serve as an optimized substrate.

This novel corneal allograft promotes regeneration of the corneal epithelium. BrightMEM is made from Descemet's membrane, which serves as an optimized substrate for protecting the stroma from degradation and promoting regeneration of the corneal epithelium.

BrightMEM expresses proteins that stimulate limbal stem cell growth while resisting degradation. In preclinical studies, BrightMEM supported limbal stem cell expansion and maintained a population of stem cells in the basal corneal epithelium.

BrightMEM offers hope as a durable solution for patients with severe corneal disorders through its regenerative properties.
